Soo Yeon Lee of Korea's Daegu Gyeongbuk Institute of Science and Technology and her colleagues report in the journal, Science, that they created the genome of the half-sized catfish, a 507 g fish, by putting together the individual strands of DNA from the embryo's cells into an "artificial chromosome" – a strand of DNA which would then be able to replicate itself. The cell of an adult catfish is about 0.15 mm in diameter, compared to the 0.2 mm diameter of human cells, and the half-sized fish cloned has a normal amount of DNA of about 4.2 billion base pairs, and not the 30 million base pairs that the human genome is said to have. Commenting on the research, Roy

---

Sohn of the University of Toronto, who was not involved in the study, says the work represents “an exciting achievement in the development of genome editing technology in general, and gene therapy in particular”. “It is likely to greatly accelerate progress in regenerative medicine and tissue engineering,” he says. “Until now, the development of pluripotent stem cell lines from animals with large genomes has not been feasible. In other words, the cloning of a full-sized adult fish is impossible because the genome of any animal is too big for a single cell.” “This novel method also paves the way for the creation of new animal models that mimic human diseases by precisely modifying the genome of the embryos,” said Lee. Other authors of the study are: Young-Ho Shin and Yong Jin Kim of the University of Incheon; Song-Hee Lee and Jae-Gyu Yoo of the Korea Research Institute of Bioscience and Biotechnology. The Japanese company, H3C, is presenting a new keyboard on CES 2016: H3C Zero. The new keyboard has several features that try to change the keyboard world. Some features that are available on the H3C Zero are: A gesture-based keyboard that is similar to the on- f3e1b3768c
