Jan 1, 2018 Samsung J5 2016 To get root on your device and install any custom ROM, you must have build.prop file on your PC. If you have the build.prop file, you can also root your phone, and then proceed to the settings menu using the power key, and from there you can flash any custom ROM of your choice. We recommend Mobile Odin. You can download a build.prop file from or you can find them from your android device's cache. Note: You can root your phone and do the same, but it's recommended to download or flash an odin file to achieve the same. Package Used in the Repairs: Package Used in the Repairs: MD5:

So I tried this and found your help page and now everything is working fine. Thanks so much. A: Samsung Galaxy J5 2016 When you bought your phone in 2016 there was a software update for you. 1. Open the Settings - Application - Software update and check if it got updated to the newest version there. If yes, ok and install it. If not, then take it to a local service center to update it by paying the extra cost. Then you will have an update in the Settings menu for that version. If not, then go to "Help" tab, click on "About Device", check if it's under version XX or not. Then go to "Software Updates" tab, search for the newest version there, and Install it. Check again if it's the newest version available or not. The next time you open the Settings - About device and check if it's the newest version there. Hope this helps.
